AMENDMENTS IN THE CLAIMS

1 1. (Currently amended) A method for enhancing signal-to-noise ratio
2 associated with a transmitted digital communication signal without affecting its power
3 flux density, the method comprising the following steps performed in a transmitter:
4 selecting a reduced information data rate that is a fraction of a full data
5 rate R, wherein the reduced information data rate is 1/4 of the full data rate R;
6 randomizing the reduced data rate information signals to produce an
7 encoded data stream at the full data rate R; and
8 transmitting the encoded data stream;
9 wherein the reduced information data rate results in an enhanced signal-
10 to-noise ratio, per bit of information, that is increased by a factor of four due to reduction
11 in the information data rate increasing the energy per bit, and wherein transmittal of the
12 encoded data stream at the full data rate ensures that power flux density will not be
13 significantly changed.

1 2. (Previously Amended) The method of claim 1, and further comprising the
2 following steps performed in a receiver:
3 receiving and demodulating the transmitted encoded data stream; and
4 recovering data at the reduced information data rate.

1 3. (Previously Amended) The method of claim 1, wherein the randomizing
2 step comprises:

3

NGC-262/22-0177

3 generating a pseudorandom noise sequence of bits at the full data rate R;
4 and
5 logically combining the pseudorandom noise sequence with the reduced
6 information data rate signals to produce the encoded data stream.

7

1 4. (Previously Amended) The method of claim 3, wherein the logically
2 combining step further comprises the step of performing a logical exclusive OR
3 operation.

4

1 5. (Previously Amended) The method of claim 3, further comprising the
2 following steps performed in a receiver:
3 generating a pseudorandom noise sequence; and
4 logically combining the pseudorandom noise sequence generated in the
5 receiver with the received data signals, to recover the signals transmitted at the reduced
6 data rate.

7

1 6. (Currently amended) A digital communication apparatus, comprising:
2 means for reducing the rate of an information data stream to be
3 transmitted from a full rate R to a selected reduced rate, wherein the selected reduced
4 rate is 1/4 of the full data rate R;
5 a pseudorandom noise source generating a stream of practically random
6 data at the full data rate R;

4

NGC-262/22-0177

means for logically combining the reduced rate information data stream
and the data stream from the pseudorandom noise generator; and

means for transmitting the logically combined data stream;

wherein signal-to-noise performance of the transmitter is enhanced
without increasing power flux density levels;

wherein the reduced information data rate results in an enhanced signal-to-noise
ratio, per bit of information, that is increased by a factor of four due to reduction in the
information data rate increasing the energy per bit.

7. (Previously Amended) The digital communication apparatus of claim 6,
wherein:

the means for logically combining comprises a logical exclusive OR circuit.

8. (Previously Amended) The digital communication apparatus of claim 6,
further comprising:

means for receiving and demodulating the logically combined data stream;
a second pseudorandom noise source located near the means for
receiving, for generating a stream of data identical with the one produced by the first
pseudorandom noise source; and

means for logically combining the demodulated data stream with the data
stream from the second pseudorandom noise source, for recovering the original data
stream at the reduced data rate.

1 9. (Previously Presented) The digital communication apparatus of claim 6,
2 wherein the means for reducing the rate of the information data stream comprises data
3 buffers used to store the information data stream.
4

1 10. (Previously Presented) The digital communication apparatus of
2 claim 6, wherein, upon input to the means for transmitting, the
3 logically combined data stream is used to modulate a carrier via
4 binary phase shift keying (BPSK).
5

1 11. (Currently Amended) A system, comprising:
2 a data rate control device operable to reduce the rate of an information
3 data stream to be transmitted from a full rate R to 1/4 of the full data rate R;
4 a pseudorandom noise source operable to generate a stream of practically
5 random data at the full data rate R;
6 a first logical exclusive OR circuit operable to combine the reduced rate
7 information data stream and the data stream from the pseudorandom noise generator;
8 a transmitter operable to send the logically combined data stream;
9 a receiver operable to demodulate the logically combined data stream;
10 a second pseudorandom noise source located near the receiver, operable
11 to generate a stream of data identical with the one produced by the first pseudorandom
12 noise source; and

13 a second logical exclusive OR circuit operable to combine the
14 demodulated data stream with the data stream from the second pseudorandom noise
15 source, to recover the original data stream at the reduced data rate;
16 wherein the reduced information data rate results in an enhanced signal-to-noise
17 ratio, per bit of information, that is increased by a factor of four due to reduction in the
18 information data rate increasing the energy per bit, and wherein transmittal of the
19 encoded data stream at the full data rate ensures that power flux density will not be
20 significantly changed.
21

1 12. (Previously Presented) The system of claim 11, wherein data rate control
2 device comprises data buffers operable to store the information data stream.
3

1 13. (Previously Presented) The system of claim 11, wherein, upon input to the
2 transmitter, the logically combined data stream is used to modulate a carrier via binary
3 phase shift keying (BPSK).
